σ -Algebra

Solution

Since \mathcal{A} is a σ -Algebra, it must be closed under complement and under countable unions. Using De Morgan's laws: $\overline{\bigcup_{i \in I} X_i} = \bigcap_{i \in I} \overline{X_i}$, we find that we can construct any intersection from unions and intersection, thus \mathcal{A} is closed under intersection as well. Given that \mathcal{A} separates points, it must contain every set of a single element, as this separates the remaining point from all others. If all singletons are in \mathcal{A} then all possible subsets of X can trivially be constructed from the operations of countable intersection, union and complement without exiting \mathcal{A} . Thus $\mathcal{A} = \mathcal{P}(X)$.

Covariance and Correlation

Solution

a)

b)

$$\varrho_{X,Y} = \frac{\text{Cov}(X,Y)}{\sigma_X \sigma_Y}$$

Using the Cauchy-Schwarz Inequality:

$$\begin{aligned} |\text{Cov}(X,Y)|^2 &\leq \sigma_X^2 \sigma_Y^2 \\ \Rightarrow |\text{Cov}(X,Y)| &\leq \sigma_X \sigma_Y \end{aligned}$$

Assuming $\sigma_X, \sigma_Y \neq 0$, divide by the product:

$$\begin{aligned} \frac{|\text{Cov}(X,Y)|}{\sigma_X \sigma_Y} &\leq 1 \\ \Rightarrow -1 &\leq \frac{\text{Cov}(X,Y)}{\sigma_X \sigma_Y} \leq 1 \\ \Rightarrow -1 &\leq \varrho_{X,Y} \leq 1 \end{aligned}$$

c)

Bernoulli Trials

Solution

a)

b) For a success on trial t we need the first $t - 1$ trials to be failures, followed by a success. Thus $P(T_1 = t) = (1 - p)^{t-1}p$.

For the second success to be on trial t , we need $t - 2$ failures with a success in between at some point and at trial t . Since we have $t - 1$ possible position for the first success, this leaves us with $P(T_2 = t) = (t - 1)(1 - p)^{t-1}p^2$.

As $X = T_2 - T_1$ describes the number of trials between the first and second success, this is identical distributed as T_1 , namely: $(1 - p)^{t-1}p$.

c)

Independance

Solution
